Common symptoms and symptom complexes are addressed by this tool. Imaging requests for patients with atypical symptoms or clinical presentations that are not specifically addressed will require physician review. Consultation with the referring physician may provide additional insight.

This version incorporates MSI accepted revisions prior to 12/18/09

ABDOMEN IMAGING GUIDELINES

AB-1~GENERAL GUIDELINES

- Imaging is the final arbiter in the evaluation and does not substitute for a careful history and physical exam along with pertinent laboratory tests. Other imaging studies should be considered such as plain film or ultrasound before advanced imaging.
- Abdominal imaging begins at the diaphragm and extends to the umbilicus or iliac crest.
- Pelvic imaging begins at the iliac crest and extends to the pubis.
- CT imaging is a more generalized modality
  - Abdominal CT is usually performed with contrast (CPT®74160). Exceptions are noted in the individual guidelines.
  - Abdominal CT without and with contrast (CPT®74170) can be considered in patients with fatty liver who have suspicion of a liver lesion.
- MRI imaging is preferred as a more targeted study, in cases of renal failure, and in patients allergic to contrast.
  - MRI of the abdomen with contrast only is essentially never performed. If contrast is indicated, MRI abdomen without and with contrast (CPT®74183) should be performed.
  - Pregnant women should be evaluated by ultrasound or MRI where it is a clinical option to avoid radiation exposure.
- Abdominal CT or MRI can be considered to further evaluate abnormalities seen on other imaging modalities such as plain x-ray, ultrasound, etc.
- **Fever of unknown origin; Unexplained weight loss**
  Refer to: ONC-28~Medical Conditions with Cancer in the Differential Diagnosis in the Oncology guidelines.
- **Suspected ascites should be initially evaluated by ultrasound.** Ultrasound results can then determine the need for peritoneal fluid analysis or further imaging specific to the findings.*
- **CODING ISSUES**
  - **CT Enterography**
    - Combines CT imaging with large volumes of ingested neutral bowel contrast material to allow visualization of the small bowel wall and lumen
    - Report CPT® 4160
    - Usually only 2D reformatting is used (coronal reformatted images)
    - If the 3D rendering codes are requested (CPT®76376 or CPT®76377), then the final radiology report should be obtained first to verify that true 3D rendering was performed.
    - Also see **AB-28 Inflammatory Bowel Disease Rule Out Crohn’s Disease or Ulcerative Colitis**.
Reference

- *RadioGraphics* 2006 May;26:641-657

CT Enteroclysis

- A tube is placed through the nose or mouth and advanced into the duodenum or jejunum. Bowel contrast material is infused through the tube and CT imaging is performed either with or without intravenous contrast.
- CT enteroclysis is used to allow visualization of the small bowel wall and lumen. CT enteroclysis may allow better or more consistent distention of the small bowel than CT enterography.
- Use CPT®74150 or CPT®74160
- Usually only 2D reformatting is used (coronal reformatted images)
- If the 3D rendering codes are requested (CPT®76376 or CPT®76377), then the final radiology report should be obtained first to verify that true 3D rendering was performed.
- Also see [AB-28 Inflammatory Bowel Disease Rule Out Crohn's Disease or Ulcerative Colitis](https://www.ncbi.nlm.nih.gov/pubmed/26955758).

MR Cholangiopancreatography (MRCP)

- MRCP imaging protocols generally include non-contrasted sequences with 3-D postprocessing such as maximum intensity projection (MIP)
- MRCP performed as a standalone procedure should be reported with CPT®74181 or the HCPCS code S8037 (3-D rendering code 76376 or 76377 can be reported with CPT®74181 but NOT with S8037)
- MRCP performed as part of a noncontrasted MRI of the abdomen protocol should be reported as CPT®74181 in conjunction with either CPT®76376 or CPT®76377.
- MRCP performed as part of a contrasted MRI of the abdomen protocol should be reported as CPT®74183 in conjunction with either CPT®76376 or CPT®76377.
- Reporting/billing a second MRI code for MRCP performed in conjunction with MRI of the abdomen is not appropriate (for example, requesting 74181 and 74183 for MRCP performed in conjunction with MRI of the abdomen is not appropriate)
- Also see: [AB-32 MR Cholangiopancreatography (MRCP)](https://www.ncbi.nlm.nih.gov/pubmed/26955758)
GENERAL ABDOMINAL SIGNS/SYMPTOMS (ALPHABETICAL ORDER)

AB-2~ABDOMINAL PAIN, NONSPECIFIC

- Ultrasound should be the initial imaging study in patients who present with right upper quadrant pain, left upper quadrant pain or epigastric pain, since ultrasound is useful in detecting gallbladder and other hepatobiliary pathology, renal lesions, ascites, splenic pathology, and sometimes adrenal lesions. If an ultrasound is nondiagnostic or an abnormality is found that warrants further imaging, the information provided by ultrasound can help determine the most appropriate advanced imaging modality (CT vs MRI vs MRCP, etc.).*  
  *ACR Practice Guidelines for the performance of an ultrasound examination of the abdomen or retroperitoneum, revised 2007

- Ultrasound should be the initial imaging study in women with ovaries or uterus intact who present with generalized abdominal pain, especially if symptoms are located predominately in the lower abdominal area, in order to rule out gynecological pathology.

- In general, if advanced imaging is indicated, MRI should be used in pregnant women with acute abdominal pain and equivocal ultrasound.*  
  *AJR 2005 Feb;184:452-458
  - In other adult patients, MRI is usually not indicated for evaluation of abdominal pain, unless guidelines under Specific Abdominal Organs are met (see AB-21 through AB-46).

- CT scans of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) can be performed for any of the following:  
  - Abnormal lab such as WBC greater than 10,000 or abnormal stool analysis  
  - Persistent fever  
  - Failure of conservative treatment for 3-4 weeks including clinical re-evaluation  
  - Documented rebound tenderness or guarding on a recent physical exam  
  - Persistent abdominal pain (greater than 4 weeks with no improvement) with unremarkable endoscopy and/or barium enema results  
  - Non diagnostic recent endoscopy and/or barium study  

- GI specialist evaluation can be helpful in determining the appropriate imaging pathway.  
  - CT scans of the abdomen and pelvis either with or without contrast (CPT®74160/72193 or CPT®74150/72192) can be performed prior to endoscopy if requested by the physician who will be performing the endoscopy, especially if there is suspected inflammatory bowel disease.

- Repeat imaging in patients with unchanged symptoms is not appropriate.

- Patients with severe abdominal pain disproportionate to clinical findings should undergo mesenteric CTA or MRA (CPT®74175 or CPT®74185) if plain x-rays and/or abdominal CT are negative (see AB- 9 Mesenteric/Colonic Ischemia).

- CT of abdomen and/or pelvis may be performed to evaluate abnormalities detected on plain abdominal x-rays that require further clarification.
AB-3~ABDOMINAL SEPSIS
(SUSPECTED ABDOMINAL ABSCESS)

- CT abdomen and/or pelvis with contrast (CPT® 74160 and/or 72193) is indicated when the patient has a palpable mass or suspicious abdominal symptoms with fever and/or elevated white blood cell count.*
  *ACR Appropriateness Criteria, Acute abdominal pain and fever or suspected abdominal abscess, 2008
- Ultrasound may be useful in follow-up of known fluid collections, especially with catheter drainage, provided the patient is stable or improving. Serial CT scans with contrast (CPT® 74160 and/or CPT® 72193) are also appropriate.

DIARRHEA/CONSTIPATION/BLOATING—SEE AB-26

AB-4~EPIGASTRIC PAIN, DYSPEPSIA, GASTRITIS, and POSTPRANDIAL FULLNESS

- Ultrasound should be the initial imaging study in patients who present with epigastric pain, since ultrasound is useful in detecting gallbladder and other hepatobiliary pathology, renal lesions, ascites, splenic pathology, and sometimes adrenal lesions. If an ultrasound is nondiagnostic or an abnormality is found that warrants further imaging, the information provided by ultrasound can help determine the most appropriate advanced imaging modality (CT vs MRI vs MRCP, etc.).*
  *ACR Practice Guidelines for the performance of an ultrasound examination of the abdomen or retroperitoneum, revised 2007
- Patients <55 years old with epigastric pain/dyspepsia should initially have 4 to 8 weeks of conservative treatment with antisecretory medication and/or H. Pylori treatment.
  - Patients who fail conservative treatment benefit from GI consultation, and upper endoscopy should be considered.
  - Non-invasive imaging is of low yield.*
    *Am J Gastro 2005;100:2324-2337
- Patients ≥ 55 years old with epigastric pain/dyspepsia who present with anemia, weight loss, progressive dysphagia, bleeding, family history of GI cancer, abnormal labs, or history of GI disease should undergo initial endoscopy.
  - Evaluation by a GI specialist should be strongly considered.
  - Advanced imaging usually proceeds based upon the GI consultation.*
    *Am J Gastro 2005;100:2324-2337
- Symptoms that fail to respond to conservative treatment with antisecretory and/or H. pylori medications should be evaluated by upper GI series or endoscopy.
  - GI consultation is helpful, and advanced imaging should not be used as the initial study unless there is clinical evidence for tumor.*
    *South Med J 2001;94(2):184-189
- If pancreatic disease is suspected, refer to AB-39~Pancreatitis
• CT of abdomen and/or pelvis may be performed to evaluate abnormalities detected on plain abdominal x-rays that require further clarification.

**AB-5~FLANK PAIN, RULE OUT RENAL STONE**

• If renal stone is not at the top of the differential diagnosis, ultrasound should be performed as the initial imaging study.
• If renal stone is at the top of the differential diagnosis, CT scans of the abdomen and pelvis without contrast (CPT®74150 and CPT®72192) are the best imaging studies in the non-pregnant patient to evaluate kidney stone.
• In pregnant patients and children, ultrasound or MR urography (MRI abdomen and pelvis, with or without contrast [CPT® 74182/72196 or CPT®74181/72195] is the best initial study to avoid radiation exposure.*
• CT urogram (CT abdomen and pelvis without and with contrast—CPT®74170 and CPT®72194) should be performed, if requested, in patients over 40 years old with flank pain and documented hematuria.
• Serial CT scans to determine the passage or dissolution (of uric acid stones) of kidney stones are acceptable if they do not exceed three scans in a six week period. If the stone has been seen on the pelvic CT portion of the CT scan, the subsequent CT scan(s) should only include the pelvis. Urology evaluation can be helpful in determining the need for serial CT scans.
• Post-procedure follow-up should be performed with x-rays of the abdomen every 6 to12 months in asymptomatic patients unless the patient had uric acid stones.*
  o Noncontrast CT abdomen and/or pelvis (CPT®74150 and/or CPT®72192) can be used to follow-up patients with uric acid stones.
  o CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) can be performed if there were surgical complications or the patient develops unusual symptoms.*
  *Wolf JS. Nephrolithiasis. eMedicine, updated September 28,2009.

**AB-6~GASTROENTERITIS**

• Gastroenteritis is generally defined as diarrhea with nausea and vomiting and usually with a viral or bacterial etiology.
• If laboratory studies and physical examination reveal an acute abdomen suggesting bowel obstruction, toxic megacolon (abdominal swelling, fever, tachycardia, elevated white blood cell count), or perforation, CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) can be performed.
• When history, physical exam and laboratory results do not suggest a specific etiology for persistent nausea and vomiting, a one to two week trial of conservative treatment, which might include antiemetics and dietary modifications, is indicated. Plain x-rays should be done to rule out bowel obstruction.
Upper GI series and/or endoscopy should be performed if there is failure to improve with conservative treatment and plain films are nondiagnostic.*

• Barium studies and/or endoscopy are indicated if diarrhea lasts more than 1 to 2 weeks, there is failure to improve with conservative treatment, GI bleeding is present, or there are abnormal labs including stool analysis and/or culture.

• GI consultation is helpful in evaluating diarrhea lasting more than 1 to 2 weeks, failure of conservative management, GI bleeding, or abnormal labs including stool analysis and/or culture.

• References:
  - Am Fam Physician 2007 July 1;76(1):76-84

| AB-7~LEFT LOWER QUADRANT PAIN, RULE OUT DIVERTICULITIS |

- Patients with known diverticulosis and/or suspected diverticulitis who present with any one of the following clinical findings: severe abdominal pain, palpable mass on examination, nausea/vomiting, fever, significant abdominal tenderness to palpation, or elevated white blood cell count, should proceed to CT of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) in order to rule out significant inflammation or complications of diverticulitis such as abscess or perforation, prior to invasive diagnostic procedures such as colonoscopy.
- Patients with diabetes, renal failure, or the very elderly should be evaluated initially with CT abdomen and pelvis with contrast (CPT®74160 and CPT®72193), or without contrast (CPT®74150 and CPT®72192) for those with renal insufficiency or renal failure.
- Medical treatment prior to imaging:
  - Patients who present with mild to moderate abdominal pain, but without significant clinical findings may benefit from a 7 to 10 day trial of antibiotic therapy and close observation prior to considering advanced imaging.
  - Patients with a previous history of diverticulitis who present with clinical symptoms of recurrent disease may not require any imaging prior to a trial of antibiotic therapy.*
    * ACR Appropriateness Criteria, Left lower quadrant pain, 2008
  - If fever, elevated WBC count, and other symptoms do not improve after 2 to 3 days of antibiotic treatment and clear liquid diet, CT scans of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) are indicated.*

© 2010 MedSolutions, Inc.
Pelvic ultrasound is the initial imaging study of choice for women of child bearing age (<45 years old) who still have ovaries or uterus intact, for detecting gynecologic abnormalities that may cause left lower quadrant pain.

- CT scans of the abdomen and pelvis either with or without contrast (CPT®74160/72193 or CPT®74150/72192) can be considered prior to endoscopy if requested by the physician who will be performing the endoscopy.

CT abdomen and pelvis with contrast (CPT®74160 and CPT®72193) are the preferred imaging tests for the evaluation of suspected complicated diverticulitis to identify extracolonic disease that might warrant an interventional procedure.

Patients with mild pain and heme positive stools or rectal bleeding should proceed to colonoscopy first, since advanced imaging with CT is rarely helpful in the initial evaluation of these patients.

References:
- Am Fam Physician 2005;72:1229-1234 and 1241-1242
- ACR Appropriateness Criteria, Left lower quadrant pain, 2008

AB-8~LEFT UPPER QUADRANT PAIN

Ultrasound should be the initial imaging study in patients who present with, left upper quadrant pain, since ultrasound is useful in detecting gallbladder and other hepatobiliary pathology, renal lesions, ascites, splenic pathology, and sometimes adrenal lesions. If an ultrasound is nondiagnostic or an abnormality is found that warrants further imaging, the information provided by ultrasound can help determine the most appropriate advanced imaging modality (CT vs MRI vs MRCP, etc.).*

*ACR Practice Guidelines for the performance of an ultrasound examination of the abdomen or retroperitoneum, revised 2007

AB-9~MESENTERIC/COLONIC ISCHEMIA

Also see PVD- 6 Mesenteric Ischemia under Aortic Disorders and Renal Vascular Disorders, and Visceral Artery Aneurysms in the Peripheral Vascular Disease Imaging Guidelines.

GI evaluation may be helpful in determining this diagnosis.

Chronic mesenteric ischemia is associated with postprandial pain and marked weight loss.

In patients with chronic postprandial abdominal pain and weight loss with a negative abdominal/pelvic CT, abdominal CTA (CPT®74175) or MRA (CPT®74185) can be obtained.*

*World J Gastroenterol 2006 May;12(20):3243-3247
Patients with minimal abdominal tenderness on physical examination and mild to moderate abdominal pain, diarrhea or lower intestinal bleeding suggesting colonic ischemia should be evaluated by barium enema or colonoscopy initially.
  - MRA/CTA are not helpful unless symptomatology is localized to the right colon and pain is out of proportion to clinical findings.*
  *Gastroenterology 2000 May;118(5):951-953

**AB-10~POST OPERATIVE PAIN WITHIN 60 DAYS FOLLOWING ABDOMINAL SURGERY**

- CT abdomen and pelvis with contrast (CPT®74160 and CPT®72193) can be performed in patients with suspected postoperative complications (e.g. bowel obstruction, abscess, anastomotic leak, etc.).
- Pregnant women should be evaluated with MRI (contrast as requested).*
- Beyond 60 days postoperatively, see AB-2 Abdominal Pain, Nonspecific.
  *ACR Appropriateness Criteria, Suspect small bowel obstruction, 2008
  *ACR Appropriateness Criteria, Acute abdominal pain and fever or suspected abdominal abscess, 2008

**AB-11~RIGHT LOWER QUADRANT PAIN, RULE OUT APPENDICITIS**

- Women of childbearing age and pregnant patients may be evaluated first with ultrasound if local expertise exists. If positive, no further diagnostic imaging is necessary. If negative or equivocal, CT with contrast (CPT®74160 and CPT®72193) or without contrast (CPT®74150 and CPT®72192) can be performed.
  - MRI without and with contrast (CPT®74183 and CPT®72197) or without contrast (CPT®74181 and CPT®72195) can be performed for pregnant patients if ultrasound is equivocal.
  - **References:**
    - AJR 2004 Sept;183:671-675
    - Radiology 2006 Mar;238(3):891-899
- If appendicitis is strongly suspected, CT of the abdomen and pelvis either with contrast (CPT®74160 and CPT®72193) or without contrast (CPT®74150 and CPT®72192) should be performed in all patients except pregnant patients (see above).*
  *ACR Appropriateness Criteria, Acute abdominal pain and fever or suspected abdominal abscess, 2008
- If appendicitis is not at the top of the differential diagnosis, then women less than 45 years old who have ovaries or uterus intact and present with right lower quadrant pain should have ultrasound of the pelvis performed initially to rule out gynecological pathology.
- If the appendix is absent, follow guidelines in AB-2~Abdominal Pain, Nonspecific.
AB-12~RIGHT UPPER QUADRANT PAIN, RULE OUT CHOLECYSTITIS

- Right upper quadrant ultrasound is generally the imaging study of choice in the patient with acute right upper quadrant pain, with or without fever, if the gallbladder has not been removed.*
  *ACR Appropriateness Criteria: Right upper quadrant pain, 2007
- In patients who have had cholecystectomy, or in patients with normal ultrasound, CT of the abdomen with contrast (CPT® 74160) can be performed.

UMBILICAL DISCHARGE – SEE AB-46~PATENT URACHUS

MISCELLANEOUS ABDOMINAL ENTITIES (ALPHABETICAL ORDER)

AB-13~ABDOMINAL LYMPHADENOPATHY

- Patients with lymphadenopathy localized to the abdomen and found incidentally on previous imaging without associated fever, weight loss, pain, GI bleeding, or other intraabdominal findings to raise the suspicion of malignancy, can have one follow-up CT abdomen with contrast (CPT® 74160) or CT abdomen and pelvis with contrast (CPT® 74160 and CPT® 72193) two months following the original imaging study.
  - If enlarged lymph node(s) persist, biopsy should be considered to establish a histological diagnosis.*
  *Am Fam Physician 2001 Jan;63(1)

AB-14~BARIATRIC SURGERY

- Patients who have had obesity surgery and present with fever, abdominal pain, abdominal distention, frequent vomiting, or suspected incisional hernia should undergo CT of the abdomen and pelvis with contrast (CPT® 74160 and CPT® 72193).
- Patients who have had obesity surgery within the past six months and present with acute or progressive shortness or breath and suspicion of pulmonary embolus should have CT of the chest with contrast (CPT® 71260) or chest CTA (CPT® 71275).
AB-15~BLUNT ABDOMINAL TRAUMA

- Significant trauma should be evaluated in the Emergency Department.
- Trauma with low probability of intra-abdominal injury (minimal pain, no peritoneal irritation on physical examination, no hemodynamic instability, no elevated AST/ALT) should have ultrasound initially and any positive findings can be further evaluated with CT abdomen and/or pelvis with contrast (CPT®74160 and/or CPT®72193).
- For more significant trauma or blunt renal trauma associated with hematuria,¹ ² CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) may be used initially to determine patients who need hospitalization for observation.³

³ ACR Appropriateness Criteria, Blunt abdominal trauma, 2008

AB-16~GAUCHER’S DISEASE

- See also PN-6.3 Gaucher’s Disease in the Peripheral Nerve Disorders guidelines
- Imaging for follow-up:
  o Patients not on enzyme therapy: MRI abdomen without contrast (CPT®74181) and MRI lower extremity without contrast (CPT®73718) every 12 to 24 months
  o Patients on enzyme therapy:
    - Not achieved therapeutic goals: MRI abdomen without contrast (CPT®74181) and MRI lower extremity without contrast (CPT®73718) every 12 months
    - Achieved therapeutic goals: MRI abdomen without contrast (CPT®74181) and MRI lower extremity without contrast (CPT®73718) every 12 to 24 months
    - Change in dose of medication or clinical complication: MRI abdomen without contrast (CPT®74181) and MRI lower extremity without contrast (CPT®73718)
  o Patients with active bone disease may require more frequent monitoring than once a year.
- References:
  o Current Medical Research and Opinion 2006;22(6):1045-1064
Patients without prior inguinal hernia surgery who present with lower abdominal or groin pain and suspected inguinal hernia may benefit from evaluation by a surgeon. Ultrasound can be helpful when physical exam is inconclusive. Ultrasound has a very high sensitivity and specificity (88%-100%) for evaluating inguinal and femoral hernias.* Ultrasound identified the pathology in a groin (either hernia or lipoma) without a palpable bulge at an accuracy of 75%.*

*Ann Ital Chir. 2002 Jan-Feb;73(1):65-68  

Patients with suspected inguinal or femoral hernia can be evaluated by CT pelvis with contrast (CPT®72193) or without contrast (CPT®72192) if requested by the referring surgeon to determine management.

Patients with known or suspected Spigelian hernia (anterior abdominal wall hernia through the semilunar line), ventral hernia, or incisional hernia can be evaluated by CT of the abdomen (and pelvis if below the umbilicus) with contrast (CPT®74160 ± CPT®72193) or without contrast (CPT®74150 ± CPT®72192) for definitive evaluation.

Patients with suspected recurrent hernia after hernia surgery can have CT of the abdomen (and pelvis if below the umbilicus) with contrast (CPT®74160 + CPT®72193) or without contrast (CPT®74150 + CPT®72192).

Sportsman’s Hernia
- A controversial clinical entity thought to account for up to 5% of all groin injuries, especially among athletes involved in kicking sports.
- Probably a chronic overuse injury involving posterior inguinal wall weakness, tearing of the transversus abdominis aponeurosis, and neuralgia.
- Conservative management is performed initially. Some elite athletes require surgical intervention.
- Ultrasound may show posterior inguinal wall bulging, but this is also seen in asymptomatic athletes.
- Advanced imaging is not indicated.
- The microtears described at surgery cannot be reliably diagnosed on imaging and therefore, this condition remains a clinical diagnosis.

Reference:
AB-18~LIPOMA

- **Subcutaneous lipoma** does not require imaging for diagnosis
  - Evaluation by a dermatologist or surgeon is helpful in determining the need for advanced imaging.
  - If the clinical exam is equivocal, ultrasound should be performed initially.
  - Noncontrast MRI can be performed if surgery is planned.
- Lipomas in other locations (not subcutaneous) should be evaluated by ultrasound or CT without and with contrast.
  - Imaging studies cannot make a reliable distinction between a lipoma and a liposarcoma.
  - Lesions with Hounsfield units less than -50 HU do not require additional imaging except for surgical planning.*
- Noncontrast MRI can be considered if ultrasound and/or CT are equivocal, or for preoperative planning. MRI shows a discrete, homogeneous fatty mass with few or no thin septa and minimal or no areas of high T2 signal.*
  * AJR 2004;182:733-739

AB-19~LOWER EXTREMITY EDEMA

- Also see PVD-7.3 Lower Extremity Edema in the Peripheral Vascular Disease guidelines.

AB-20~ZOLLINGER-ELLISON SYNDROME (ZES)

- The initial imaging for evaluation of elevated serum gastrin (normal value is <100 pg/ml) and/or abnormal gastric acid secretory test should be Somatostatin Receptor Scintigraphy (sensitivity of >95%).
  - If the serum gastrin is not elevated and there is no abnormal gastric acid secretory test, then no advanced imaging is needed.
- Surgical consultation is helpful in determining the appropriate imaging pathway.
- CT abdomen with contrast (CPT®74160) or MRI abdomen without and with contrast (CPT®74183), have a specificity approaching 100%, but sensitivity of only 20%-59% in detecting gastrinoma.
- **References:**
SPECIFIC ABDOMINAL ORGANS

AB-21~ADRENAL CORTICAL LESIONS

- **AB-21.1 Adrenal Cortical Lesions**
  - CT of the abdomen without contrast (CPT®74150) is the imaging study of choice in patients with no history of malignancy, no symptoms, and a lesion less than 3 cm.
    - If the Hounsfield number is less than 10 HU, malignancy is unlikely and no follow-up is required.*
      *J Clin Endocrinol Metab 2005 Feb;90(2):871-877
    - If CT with washout or MRI defines the lesion as a benign lesion-adenoma, myelolipoma, hematoma or cyst, follow-up imaging is not indicated.*
      *AJR 2007;189:1119-1123
      *AJR 2008 May;190:1163-1168
  - Resection or biopsy should be considered for mass lesions larger than 4 cm or hormone-secreting tumors should be resected.*
    *ACR Appropriateness Criteria, Incidentally discovered adrenal mass, 2009
    *AJR 2005;185:684-688
  - If the lesion cannot definitely be characterized as a benign adenoma on noncontrast CT, CT of the abdomen with contrast (CPT®74160) with washout calculated can be performed to help distinguish benign adenoma from other lesions such as metastases.
    - If CT is contraindicated, chemical shift MRI (CPT®74181) can be performed.
    - Noncontrast CT (CPT®74150) and chemical shift MRI (CPT®74181) have comparable performances in the evaluation of lipid content.
    - If prior imaging is available and the lesion has been stable for at least one year, the lesion can be considered benign and no imaging follow up is indicated*
    - If the lesion has increased in size from the previous imaging, adrenal biopsy or resection should be considered.*
      *ACR Appropriateness Criteria, Incidentally discovered adrenal mass, 2009
  - **INDETERMINATE LESION:** CT of the abdomen with washout (CPT®74160) can be performed. MRI will not add significant information and MRI is not indicated unless there is a history of malignancy of a cell type that would reasonably spread to the adrenals or there is evidence of a hormone-secreting adrenal tumor.
    - If the lesion shows washout features of an adenoma, follow-up noncontrast CT of the abdomen (CPT®74150) can be performed in 12 months.¹
    - If the lesion does not show washout features of an adenoma, PET (CPT®78812 or CPT®78815) can be performed or biopsy should be considered.¹
    - Endocrine re-evaluation should be performed at one year.²
      ¹J Clin Endocrinol Metab 2005;90(2):871-877
If CT is contraindicated and MRI is indeterminate, follow-up noncontrast abdominal MRI (CPT® 74181) at 3 to 6 months, and at 12 months from the initial finding of the lesion can be performed.

In the oncology patient, CT without and with contrast (CPT® 74170) (malignant lesions show slow enhancement with delayed washout after IV contrast) or MRI of the abdomen (contrast as requested; default CPT® code 74183) is appropriate for evaluation of an adrenal lesion.

- Biopsy may be considered if pheochromocytoma is excluded.

**AB-21.2 Adrenal Endocrine Tumors**

- In patients with signs/symptoms of an adrenal cortical endocrine syndrome (e.g. Cushing’s syndrome, Conn’s syndrome), evaluation may include dexamethasone suppression, serum ACTH level, serum aldosterone/renin, and/or virulizing hormone levels, and 24 hour urine for adrenal hormones.*

  - Normal Values:
    - Aldosterone: 3-10 ng/dl (supine); 5-30 ng/dl (upright)
    - Cortisol: at 8am: 250-850 nmol/L
      at 4pm: 110-390 nmol/L
      at 10pm: 50% of 8am value

- CT with bolus arterial phase (CPT® 74160) can be performed if lab studies confirm adrenal cortical endocrine syndrome*  
  *J Clin Endocrinol Metab 2008 Sept;93(9):3266-3281

- **Pheochromocytoma**
  - Signs/symptoms include flushing spells and/or poorly controlled hypertension.
  - Elevated plasma metanephrines support the diagnosis of pheochromocytoma.
  - If plasma metanephrines are not elevated, a 24-hour urine for catecholamine and metanephrine levels should be obtained prior to considering advanced imaging.
  - If catecholamine and metanephrine levels are not elevated in a 24-hour urine, then no advanced imaging is indicated unless unexplained symptoms suggestive of pheochromocytoma persist.¹ ²
  - If possible, 24-hour urine for catecholamines and metanephrines should be obtained after an episode of sign/symptoms (e.g. following a hypertensive crisis).
    - Sensitivity for diagnosing pheochromocytoma is 99.7% with this approach.¹ ²

- Chemical shift MRI (CPT®74181) is the preferred imaging study for possible pheochromocytoma, since the tumor lights up brightly on T2 weighted images; however MRI abdomen (contrast as requested) can be performed.
- In patients with elevated catecholamines/metanephrines, great care should be exercised when considering IV contrast administration. These patients are known to have hypertensive crises with the bolus injection of IV contrast.

**AORTA**

**AB-22~ABDOMINAL AORTIC ANEURYSM (AAA), ILIAC ARTERY ANEURYSM (IAA), and Visceral Artery Aneurysms-FOLLOW UP of KNOWN ANEURYSMS and PRE-OP EVALUATION**

- **AB-22.1 Abdominal Aortic Aneurysm (AAA)**
  - Also see PVD-6 Aortic Disorders, Renal Vascular Disorders, and Visceral Artery Aneurysms in the Peripheral Vascular Disease Imaging Guidelines.
  - Ultrasound is the preferred initial imaging study in the non-obese patient to screen for AAA or to evaluate a pulsatile abdominal mass.
  - The US Preventive Services Task Force (USPSTF) recommends a one-time screening for AAA by ultrasound in men aged 65 to 75 who have ever smoked and recommends against routine screening for AAA in women.
  - The Society for Vascular Surgery and the Society for Vascular Medicine and Biology recommend yearly ultrasound studies for aneurysms between 3 to 4 cm, ultrasound studies every 6 months if aortic diameter is between 4 to 4.5 cm, and referral to a vascular specialist if aortic diameter is greater than 4.5 cm. or aortic diameter has increased in size by 0.7 cm in six months or at least 1 cm in a year*
    - *The Internet Journal of Thoracic and Cardiovascular Surgery 2006;7(2)*
    - *N Engl J Med 2002 May;346:1437-1444*
    - *Am Fam Physician 2006 April;73:1198-1206*
  - Patients with AAA's smaller than 4 cm in diameter should be followed by ultrasound every 2 to 3 years.*
    - *Cardiosource Review Journal November 2006, pp.73-77*
    - *Circulation 2006;113:463-465*
  - CT of the abdomen with contrast (CPT®74160) is indicated to follow asymptomatic obese patients using the same imaging timeline used for ultrasound in non-obese patients.
  - CT of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) can be performed if there is new onset of abdominal pain in a patient with a known AAA.
There is insufficient evidence-based data to support using advanced imaging to screen for thoracic aortic aneurysm in patients with known abdominal aortic aneurysm.

Preoperative imaging if endovascular or open repair of AAA is being considered: CT of the abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) or CTA (CPT®74175 and CPT®72191). The without contrast portion can help evaluate thrombus and calcification in the aneurysm.

• **AB-22.2 Iliac Artery Aneurysm (IAA)**
  - Iliac artery aneurysms are most commonly associated with aortic aneurysms.
  - Isolated IAA’s are rare.
    - The incidence is estimated to be 6.58/100,000 for men and 0.26/100,000 for women in the U.S.¹
  - Isolated IAA’s are frequently bilateral at time of presentation.
  - The majority of patients are male and between 50 and 70 years old.²
  - The normal size of the iliac artery is <1cm. IAA’s rarely rupture when <2cm.²
  - The average size of an IAA is 4 to 5 cm, and the average size of a ruptured aneurysm is estimated at 6 cm.¹
  - Surgical intervention should be considered when an IAA exceeds 3 to 4 cm.²
  - Evaluation of a suspected IAA should begin with ultrasound.
    - If ultrasound is equivocal, CT pelvis with contrast (CPT®72193) can be performed.
  - If IAA is found, referral to a Vascular surgeon is appropriate.
    - Follow-up imaging studies can be performed at the discretion of the vascular specialist.
  - Preoperative imaging: at the discretion of the operating surgeon

• **AB-22.3 Visceral Artery Aneurysm**
  - See PVD-6 Aortic Disorders and Renal Vascular Disorders and Visceral Artery Aneurysms in the Peripheral Vascular Disease guidelines

---

**AB-23~ABDOMINAL AORTIC ANEURYSM (AAA) and ILIAC ARTERY ANEURYSM (IAA)--POST ENDOVASCULAR or OPEN AORTIC REPAIR**

- **Open Aortic repair:**
  - Surveillance CT of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) should be performed every 3 to 5 years after open repair of a AAA to screen for aneurysms in the remaining aorta.*
    *Am Fam Physician 2006;73:1198-1204 and 1205-1206

- **Endovascular (Stent) Aortic repair:**
  - Postoperative imaging of patients who have undergone endovascular repair can include CT of the abdomen and pelvis (contrast as requested, although without and with contrast [CPT®74170 and CPT®72194] is the usual), CTA of
the abdomen and pelvis (CPT®74175 and CPT®72191), or MRA of the abdomen and pelvis (CPT®74185 and CPT®72198), although MRA is not the preferred study.

- Routine imaging studies are obtained at 1 month, 6 months, and 12 months following repair, then every year.*
- An additional study at 3 months can be performed if there was evidence of endoleak on the 1 month study.
  *Perspect Vasc Surg Endovasc Ther 2007;19:395-400

- **Iliac Repair:**
  - In patients who are status post endovascular repair of an isolated IAA, ultrasound, CT pelvis (CPT®72193 or CPT®72194), or CTA pelvis (CPT®72191) can be performed every 6 months.*

GI consultation is helpful in determining the appropriate imaging pathway.
If advanced imaging is indicated, CT scans of abdomen and pelvis with contrast (CPT^®74160 and CPT^®72193) are appropriate.

References:
- *Gastroenterol* 1999;116:1461-1463
- *Gastroenterol* 2004;127:287-293

**Constipation** in the absence of family history of inflammatory bowel disease or cancer, onset of constipation after age 50, acute onset of constipation in the elderly, GI bleeding, fever, substantial pain, vomiting, weight loss, rectal pain, abnormal lab studies, or abnormal physical examination findings should be treated conservatively and advanced imaging is not indicated.
Patients who fail to respond to treatment or have any of the above abnormal findings should undergo barium enema or endoscopy.
GI consultation is helpful in determining the appropriate imaging pathway.

References:
- *Am Fam Physician* 2002 June;65(11):2283-2290

MRI Defecography for constipation should be considered investigational. It may be appropriate if ordered for preoperative evaluation for the planning of complex pelvic reconstruction.*

*Obstet Gynecol* 2004;103:41-46
*Radiographics* 2002;22:817-832

**Bloating and/or Irritable bowel syndrome**
Irritable bowel syndrome is frequently a diagnosis of exclusion and is often associated with bloating or abdominal fullness.
The criteria for making the clinical diagnosis includes the following:
- Abdominal pain
- Onset of symptoms associated with a change in frequency of stool (diarrhea, constipation or both)
- Onset of symptoms with an associated change in the form of stool.
- Relief of symptoms with defecation
If the above symptoms occur in a patient under age 50 and are associated with alarm symptoms such as fever, anemia, weight loss, GI bleeding, frequent nocturnal symptoms, or failure of a 6-8 week trial of conservative therapy, work-up should include laboratory studies and flexible sigmoidoscopy prior to considering advanced imaging.
Patients ≥ age 50 with or without alarm symptoms should be evaluated with endoscopy initially.
GI consultation is helpful in determining the appropriate imaging pathway, since advanced imaging is often not indicated in these patients.

References:
- *Am Fam Physician* 2003 May;67(10):2157-2162
AB-27~GI BLEEDING

- GI bleeding should be evaluated initially by endoscopy or barium studies unless endoscopy is contraindicated.*
  *Gastroenterol 2000;118:197-200

AB-28~INFLAMMATORY BOWEL DISEASE RULE OUT CROHN’S DISEASE or ULCERATIVE COLITIS

- Colonoscopy or barium studies are the preferred imaging studies for the initial evaluation of suspected early Crohn’s disease or ulcerative colitis when pathology is limited to the mucosa.
- CT of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) are the best studies for assessing mesenteric and extra-intestinal extent of disease.
- CT of the abdomen and pelvis with contrast (CPT®74160 and CPT®72193) are the best studies for evaluation of possible abscess, bowel perforation, fistula formation, or acute inflammation in the patient with known Crohn’s disease or ulcerative colitis and an acute exacerbation (abdominal pain).
  - GI specialists’ requests for CTA of the abdomen and pelvis (CPT®74175 and CPT®72191) may be honored
- Endoscopic ultrasound, rectal ultrasound or MRI (CPT®72197) may be considered in the setting of rectal pathology (either inflammatory or neoplastic) to evaluate for peri-rectal involvement.
- Suspected small bowel Crohn’s should be initially evaluated with small bowel follow through (SBFT), barium study, and/or ileoscopy. If these are inconclusive or if obstructive disease is expected, CT enteroclysis (CPT®74150 or CPT®74160) or CT enterography (CPT®74160) may be considered. Also see bullet point regarding Coding Issues in AB-1~General Guidelines.
  - Capsule Endoscopy (CPT®91110) may be considered if SBFT and/or ileoscopy are inconclusive, and NON-obstructive small bowel Crohn’s is present. Capsule endoscopy is particularly effective for detecting proximal and early mucosal disease.*
    *Radiology 2006 Jan;238(1):128-134
  - If advanced imaging is indicated, MRI Enterography (CPT®74183) may be performed, especially in young patients to avoid radiation, to monitor response to immunomodulatory agents, and to differentiate acute phase disease from remission.*
    *Curr Opin Gastroenterol 2008 March;24(2):135-140
- SPECT and PET are considered investigational.*
AB-29~CELIAC DISEASE (SPRUE)

- Autoimmune disease in which the villi of the small intestine are damaged from eating gluten (found in wheat, barley, and rye).
- Diagnosis is made with blood tests (anti-tissue transglutaminase antibody [anti-tTG], anti-endomysium antibody (EMA), total IgA count, CBC to detect anemia, ESR, C-reactive protein, complete metabolic panel, vitamin D, E, B12 levels)
  - The tTG and EMA tests are very accurate in the diagnosis of celiac disease. If these tests are positive, endoscopy and biopsy of the small bowel is performed to confirm the diagnosis.
- Imaging studies:
  - Imaging studies are generally not indicated for the majority of patients with known or suspected celiac disease.
  - In cases of refractory celiac disease, advanced imaging such as CT or enteroclysis may be indicated in order to rule out other entities such as intestinal lymphoma and other bowel cancers. These patients are usually under the care of GI specialists.
    - If the patient has been adherent to a gluten free diet but experiences new or continued weight loss, diarrhea, abdominal distention, or anemia, CT abdomen and pelvis with contrast (CPT® 74160 and 72193) can be performed.
- Reference:

AB-30~CT COLONOGRAPHY (CTC)

- Certain payers consider CTC investigational and their coverage policies will take precedence over MedSolutions’ guidelines. Prior authorization does not guarantee payment of the study.
- CTC for Screening (CPT®74263):
  - CTC can be used for screening for colorectal cancer (CRC) every 5 years in average-risk individuals age 50 years or older.
    - Average risk is defined as:
      - Individuals with no history of adenoma and inflammatory bowel disease and negative for first degree family history of CRC.*
    - *CA Cancer J Clin 2008;58:130-160
- CTC for Diagnosis (CPT®74261 [without contrast—use as default CPT code] or CPT®74262 [with contrast, including noncontrast images if performed]) can be used in:
  - Patients who have failed conventional colonoscopy (e.g. due to a known colonic lesion, structural abnormality or technical difficulty)
Patients who have met the criteria for conventional colonoscopy but conventional colonoscopy is medically contraindicated.

Intravenous contrast is not usually used for routine CTC, but the American College of Radiology (ACR) states that “a contrasted diagnostic CTC study may be useful in some patients after incomplete endoscopy to characterize indeterminate colonic masses or to better visualize colonic segments with excess fluid.”

Reference:

LIVER

AB-31~CIRRHOSIS AND LIVER SCREENING FOR HEPATOCELLULAR CARCINOMA (HCC); LIVER TRANSPLANT

- Hepatitis B carriers with or without cirrhosis, non-hepatitis B patients with cirrhosis, and any patient with high risk for hepatocellular carcinoma (HCC) should undergo liver screening with ultrasound every 6 to 12 months.
  - Any liver lesion less than 1 cm should be followed with ultrasound every 3 to 6 months for 2 years and, if stable, ultrasound should be performed every 6 to 12 months.
  - Liver lesions over 1 cm should be evaluated per AB-34 Liver Lesion Characterization

- A liver lesion that is negative on biopsy should be followed with ultrasound or CT abdomen without and with contrast (CPT®74170) every 3 to 6 months until the lesion resolves, displays diagnostic characteristics of HCC, or repeat biopsy is positive for HCC.

Reference:
- Hepatology 2005 Nov;42(5):1208-1236

- If the criteria outlined above are fulfilled, and the provider is requesting a CTA abdomen (CPT®74175), rather than (and not in addition to) the conventional CT abdomen (CPT®74170), CTA abdomen (CPT®74175) may be authorized.

- Any suspicious findings on CT scan should be evaluated with MRI of the abdomen without and with contrast (CPT® 74183).

Liver Transplant:
- Individuals on the liver transplant waiting list can undergo advanced imaging per that institution’s protocol as long as the studies do not exceed the following:
CT or MRI abdomen (CPT®74170 or CPT®74183) every three months*
CT chest (CPT® 71260) for initial placement on the transplant list but repeat chest CT scans are not required*
MRI Bone Marrow Blood Supply (CPT®77084) or bone scan one time.

Preoperative studies immediately prior to liver transplant:
CT or MRI abdomen (CPT®74170 or CPT®74183)—if CT abdomen was most recently done while on the transplant waiting list, then MRI abdomen should be done immediately prior to transplant and vice versa
CT pelvis (CPT®72193)
CTA abdomen (CPT®74175) or MRA abdomen (CPT®74185)*
*RadioGraphics 2004;24:1367-1380
CT chest (CPT® 71260)
MRI Bone Marrow Blood Supply (CPT®77084) or bone scan

Postoperative studies:
CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) can be performed for the following:
- Unexplained fever, abdominal pain, anemia, bleeding, weight loss, lymphadenopathy, enlarged spleen or liver, or other suspected postoperative complication
Biopsy of the involved organ should be performed if Post Transplant Lymphoproliferative Disease (PTLD) is suspected
Routine use of imaging is not recommended to screen for PTLD
Reference:
- CTA (CPT®74175) or MRA (CPT®74185) abdomen may be done for preoperative evaluation of the liver for the removal of tumors or for liver transplant surgery.
  Also see ONC~13 Upper GI Cancers in the Oncology Imaging Guidelines.
  Reference:
- RadioGraphics 2004;24:1367-1380

AB-32~MR CHOLANGIOPANCREATOGRAPHY (MRCP)
- MRCP is an alternative to endoscopic retrograde cholangiopancreatography (ERCP) for evaluating the biliary system and pancreatic ducts.
  - ERCP is the gold standard and can be used for therapeutic intervention.
  - MRCP should not be used if there is a high probability of biliary obstruction based on CT or endoscopic ultrasound (EUS) and therapeutic intervention will likely be needed. In this situation ERCP should be used.
- Coding guideline for MRCP--See AB-1~General Guidelines.
- Indications for MRCP:
Rule out pathology in the biliary system or pancreatic duct when ERCP or other invasive interventional procedure is being considered but the pre-procedure suspicion of the need for therapeutic intervention is not high enough to warrant performing ERCP initially

- Examples include:
  - Suspected or known gallstone pancreatitis
  - Suspected biliary pain with low probability of common duct stone
  - Pancreatic pseudocyst
  - Pancreatic trauma
  - Recurrent acute pancreatitis with no known cause

Preoperative planning

- Evaluation of congenital anomaly of pancreaticobiliary tract
- Altered biliary anatomy that precludes ERCP (e.g. post-surgical distorted anatomy)
- Failed ERCP in a patient who needs further investigation
- Evaluation of pancreaticobiliary anatomy proximal to a biliary obstruction that cannot be opened by ERCP
- ERCP is indicated but is not available, is contraindicated, or is expected to be difficult
  - Examples include coagulopathy, severe cardiopulmonary disease, allergy to iodinated contrast, distorted anatomy, pregnant patient

- References:
  - BMC Medical Imaging 2006;6:9
  - Cigna Medical Coverage Policy 0306, Magnetic Resonance Cholangiopancreatiography (MRCP). February 15, 2009

### AB-33~JAUNDICE

- Ultrasound is the preferred initial imaging study for patients with obstructive jaundice (i.e. high direct or conjugated bilirubin level) to visualize the biliary ductal system, and often demonstrates the level and cause of any obstruction.
  - Normal Values:
    - Bilirubin (total) 0.2-1.0 mg/dl
    - Bilirubin (conjugated) 0-0.2 mg/dl
- CT of the abdomen without and with contrast (CPT® 74170) is preferred in obese patients, patients with large amounts of intestinal gas, patients who present with painless jaundice, or patients who present with acute abdominal pain and one of following: fever, previous biliary surgery, or known cholelithiasis.
- MR cholangiopancreatography (MRCP See AB-1~General Guidelines for coding guidelines for MRCP) may be used to assess the extent and cause of intrahepatic bile duct obstruction suggested by either ultrasound or CT if further characterization is warranted. MRCP can help identify the course and drainage pattern of the pancreatic duct and is useful in diagnosing congenital anomalies such as pancreas divisum, and annular pancreas, and in detection of strictures, fistulas, and intraductal calculi prior to surgery.
MRCP is also useful when there are contraindications to the use of IV contrast for CT imaging. Specialist evaluation is helpful in determining the need for MRCP.

Abdominal CT without and with contrast (CPT®74170) or abdominal MRI with MRCP (CPT®74183 and CPT®76376 or CPT®76377) See AB-1~General Guidelines for coding guidelines for MRCP performed in conjunction with abdominal MRI) for patients with contraindications to CT* can be used to evaluate jaundice with high likelihood of malignancy (insidious onset, weight loss, fatigue).

*ACR Appropriateness Criteria, Jaundice, 2008

**AB-34~LIVER LESION CHARACTERIZATION**

- Suspected hepatomegaly should be evaluated by ultrasound initially.
- A suspected liver lesion should be evaluated by ultrasound initially.
- A liver lesion with typical ultrasound and/or contrast enhanced CT features of a simple cyst or hemangioma may be classified as benign and does not require follow-up imaging.*
  

- A liver lesion with typical CT features of a malignant mass does not require additional imaging. Confirmation with biopsy under ultrasound or CT guidance is indicated.

- PET scan is not indicated to evaluate a liver lesion in a patient with no prior history of confirmed malignancy.

**AB-34.1 Hemangioma**

  - If a lesion >1cm is found as an incidental finding on ultrasound or other imaging, triple phase CT (CPT®74170) is preferred to confirm a suspected hepatic hemangioma.*
    
    *Hepatology 2005 Nov;42(5):1208-1236

  - Most hemangiomas are easily diagnosed with CT scan.
  - MRI of the abdomen without and with contrast (CPT®74183) should be reserved for equivocal lesions.
    - In one study, the diagnosis of hemangioma was established by ultrasound in 57% of patients, by CT scan in 73%, and by MRI in 84%.*
      
      *J Am Coll Surg 2003 Sep;197(3):392-402

  - CT angiography of the abdomen (CPT®74175) is useful as a preoperative study in patients with large hemangiomas considered for resection.

**AB-34.2 Hepatic Adenoma or Focal Nodular Hyperplasia**

  - MRI of the abdomen without and with contrast (CPT®74183) is the imaging study of choice to evaluate a possible hepatic adenoma or focal nodular hyperplasia (FNH).
  - For FNH lesions being followed by serial imaging, MRI of the abdomen without and with contrast (CPT®74183) can be performed annually for 3 years. If no changes occur, imaging is discontinued.
    - Lesions greater than 3 cm should be biopsied for definitive diagnosis.*
**AB-34.3 Cirrhotic Liver**
- An indeterminate liver lesion in a cirrhotic liver is best evaluated with MRI of the abdomen without and with contrast (CPT®74183).

**AB-34.4 Nonalcoholic Fatty Liver Disease (NAFLD):**
- Ultrasound is the preferred imaging study to evaluate for biliary disease or isolated liver lesion.
- Distinguishing between fatty liver and steatohepatitis is made via biopsy rather than advanced imaging. Imaging (US, CT or MRI) is not useful to differentiate benign steatosis from steatohepatitis.*
  *Gastroenterology 2002 Nov;123(5):1705-1725
  *Internal Medicine Journal 2004;34:187-191
  *CMAJ 2005 March;172(7):899-905

**AB-34.5 Liver Lesion <1 cm**
- Any Liver lesion less than 1 cm should be followed with ultrasound every 3 to 6 months for 2 years: if stable, ultrasound should be performed every 6 to 12 months.

**AB-34.6 Liver Lesion ≥1 cm**
- Liver lesions ≥1cm may be evaluated by CT abdomen without and with contrast (CPT®74170) or MRI abdomen without and with contrast (CPT®74183).
- If the lesion appearance is typical of hepatocellular carcinoma (HCC), the lesion should be treated as HCC.
- If further characterization of a one centimeter or larger liver lesion found on CT is needed, MRI of the abdomen without and with contrast (CPT®74183) can be performed.
- Lesions that are unable to be characterized as either benign or typical of malignancy on CT or MRI should be biopsied.
- Lesions ≥1cm with a negative biopsy can have repeat ultrasound or CT abdomen without and with contrast (CPT®74170) every 3 to 6 months until the lesion resolves, displays diagnostic characteristics of HCC, or repeat biopsy is positive.
- Reference:
  - Hepatology 2005 Nov;42(5):1208-1236

---

**AB-35~ELEVATED LIVER FUNCTION (LFT) LEVELS**

- The enzymes included in this category are AST, ALT, alkaline phosphatase, GGT, and bilirubin.
- Patients with elevation of AST and/or ALT less than two times normal should have repeat levels performed in three to four weeks prior to considering advanced imaging.
- Patients on lipid lowering medications (statins) or other substances known to cause elevated LFT’s should have those substances stopped for at least 8 to 12 weeks and the LFT levels repeated prior to considering advanced imaging.
Examples of hepatotoxins include alcohol, niacin, sulfa, rifampin, tetracycline, estrogen, acetaminophen, etc.

- Patients with persistently elevated LFT’s or LFT’s less than three times normal should have ultrasound as the initial imaging study.
  - If a liver or pancreatic mass is seen, CT of the abdomen without and with contrast (CPT® 74170) is appropriate.
  - If biliary dilatation or other nonspecific abnormality is seen, CT of the abdomen with contrast (CPT® 74160) is appropriate.
- Patients with LFT’s greater than or equal to three times normal can have CT of the abdomen with contrast (CPT® 74160).
- If biliary dilatation is seen on ultrasound or CT, MRCP (See AB-1 General Guidelines for coding guidelines for MRCP) may be appropriate.
  - Specialist evaluation can be helpful in determining the need for MRCP because ERCP is both diagnostic and therapeutic if biliary stone is a high probability.
- Patients with known cancer and suspected liver metastases should have CT of the abdomen without and with contrast (CPT® 74170) or CT of the abdomen with contrast (CPT® 74160) (whichever the physician prefers). Default CPT® code should be CPT® 74170.
- Patients with elevated alpha-fetoprotein (AFP) levels should have MRI of the abdomen without and with contrast (CPT® 74183).
- CT of the abdomen with contrast (CPT® 74160) is appropriate in patients who present with painless jaundice. MRI/MRCP (See AB-1 General Guidelines for coding guidelines for MRCP performed in conjunction with abdominal MRI) are accurate but should be reserved for patients with contraindications to CT.*
  *ACR Appropriateness Criteria, Jaundice, 2008

- Hemochromatosis:
  - The diagnosis is made by biopsy.
  - Specialist (GI or Hematologist) evaluation is helpful.
  - MRI without contrast (CPT® 74181) is used to confirm liver iron stores and for following treatment.*
  *Hepatology 2001;33(5):1321-1328
AB-36~RULE OUT LIVER METASTASIS

- CT of the abdomen with contrast (CPT®74160) is a sensitive modality that is preferred to MRI to screen for liver metastasis and/or metastases in the adrenal glands, retroperitoneum, and other abdominal organs.
- MRI of the abdomen without and with contrast (CPT®74183) can be used to image lesions that are indeterminate on CT scan or if CT is contraindicated.
- MRI of the abdomen without and with contrast (CPT®74183) should be considered as the initial imaging study in the setting of elevated AFP with a suspected liver lesion. CT of the abdomen without and with contrast (CPT®74170) can be approved if requested by the physician’s office.

PANCREAS

AB-37~PANCREATIC LESION

- Screening studies for pancreatic cancer
  - See bullet on Screening studies for pancreatic cancer in: ONC-12 Pancreatic Cancer in the Oncology Imaging Guidelines
- Pancreatic cyst, incidental:
  - For pancreatic cystic lesions < 1cm in size, thin slice abdominal CT (CPT®74170) is indicated one year from the original discovery and then every year
    - MRI and CT demonstrate similar accuracy in differentiating malignant from benign cystic pancreatic lesions
  - Pancreatic cystic lesions measuring 1-2 cm should be evaluated by endoscopic ultrasound (EUS) and MRCP or ERCP
    - If EUS and MRCP or ERCP do not show mural nodules, dilated main duct (>6mm), or positive cytology, and pancreatitis, worsening of diabetes or jaundice are not present, then abdominal CT (CPT®74170) can be performed as follows:
      - Every 6-12 months for lesions measuring 1-2 cm
      - Every 3-6 months for lesions measuring 2-3 cm
  - Pancreatic cystic lesions should be resected if any of the following apply:
    - Lesions > 3cm
    - Evidence of mural nodules
    - Dilated main duct
    - Positive cytology
    - Development of pain
    - Worsening diabetes
    - Jaundice
    - Preoperative imaging studies should be requested by the operating surgeon
- Reference:
  - Pancreatology 2006;6:17-32
**Pancreatic mass or suspected metastatic disease to pancreas:**
- CT abdomen with contrast with triphasic imaging (CPT®74170), or CT abdomen without and with contrast (CPT®74170) is indicated to evaluate a pancreatic mass, since the majority of primary pancreatic tumors and other tumors metastatic to the pancreas will enhance following IV contrast.*
- For pancreatic necrosis following pancreatitis, CT abdomen with contrast (CPT®74160) or without contrast (CPT®74150) can be performed.*
  *ACR Appropriateness Criteria, Acute Pancreatitis, 2006
- MRI of the abdomen without and with contrast (CPT®74183) may be useful in cases where CT scan is contraindicated. MRI is no more accurate than CT for the follow-up of pancreatic cystic lesions.

### AB-38~PANCREATIC PSEUDOCYSTS

- There are no established guidelines for the serial imaging of pancreatic pseudocysts. CT of the abdomen with contrast (CPT®74160) should be obtained initially.*
  - In patients with minimal symptoms, CT of the abdomen with contrast (CPT®74160) or without and with contrast (CPT®74170) every two weeks or so up to six weeks total can be obtained.
  - After six weeks, CT scan should be every four weeks.
  - Abdominal CT without and with contrast (CPT®74170) can be obtained earlier if symptoms worsen, if ascites or pleural effusion develops, if serum amylase increases, or if drainage of the cyst is planned.
  - Endoscopic ultrasound has increasingly become an important imaging modality in evaluating pseudocysts.
    *Federle MP and Anne VS. Pancreatic pseudocyst. In Federle MP, Jeffrey RB, Desser TS, et. al. (Eds.). Diagnostic Imaging Abdomen, 1st Ed. Salt Lake City, Amirsys and Elsevier Publishers, 2004, pp. II;3;24-25
- MR cholangiopancreatography (MRCP—See AB-1 General Guidelines for coding guidelines for MRCP) may be obtained for preoperative planning if cyst drainage is being considered.
- MRCP is useful in detecting or excluding pancreatic duct trauma and pseudocysts in patients with pancreatic trauma.
**Suspected Pancreatitis:**
- Symptoms of mild epigastric pain described as uncomfortable without guarding should be evaluated initially by ultrasound and serum lipase/amylase.
- If amylase/lipase are elevated but are less than three times the upper limits of normal, and ultrasound does not demonstrate an abnormality to explain the signs and symptoms (e.g. gallstones, common duct stone, etc.), then CT abdomen with contrast (CPT®74160) can be performed.
- If ultrasound suggests pancreatitis, then advanced imaging is not necessary.
- Reference:  
  - *Am J Gastroenterol* 2006;101:2379-2400

**Known Acute Pancreatitis:**
- The diagnosis of acute pancreatitis is made by fulfilling two of the following three conditions:
  - 1) Typical pain (acute onset of epigastric pain radiating to the back that is persistent without relief, frequently associated with nausea and vomiting, and associated with severe epigastric tenderness and/or guarding)
  - 2) Lipase and/or amylase greater than or equal to three times the upper limit of normal
  - 3) Typical characteristics of pancreatitis on CT abdomen
- If the diagnosis of acute pancreatitis is made based on 1) and 2) above, then advanced imaging is not indicated except in the following circumstances:
  - CT abdomen with contrast (CPT®74160) or without contrast (CPT®74150) can be performed if there are suspected intraabdominal complications in patients with severe, acute pancreatitis. These complications include peripancreatic effusions, pseudocysts, abscess, and pancreatic necrosis.
  - MRI without and with contrast (CPT®74183) can be obtained if CT is contraindicated or equivocal.
  - Patients with an elevated amylase (normal range 0-99 U/L) or lipase level [normal range 0-59 U/L]) greater than or equal to three times normal who have any of the following: fever, elevated WBC, palpable mass, or who do not improve with medical therapy should have a CT abdomen with contrast (CPT®74160).
  - MR cholangiopancreatography (MRCP—See **AB-1 General Guidelines for coding guidelines for MRCP**) should be considered for:
    - Patients with known or suspected gallstone pancreatitis to screen for those patients who would benefit from ERCP.
    - Patients with recurrent, acute pancreatitis with no known cause.
    - MRCP can help identify the course and drainage pattern of the pancreatic duct and is useful in diagnosing congenital
anomalies such as pancreas divisum and annular pancreas, and in the detection of strictures, fistulas, and intraductal calculi prior to surgery. MRCP is also useful when there are contraindications to the use of IV contrast for CT imaging.

- Specialist evaluation is helpful in determining the need for MRCP.

- References:
  - Am J Gastroenterol 2006;101:2379-2400
  - Am Fam Physician 2007 May;75(10):1513-1520
  - ACR Appropriateness Criteria, Acute Pancreatitis, 2006

- Chronic Pancreatitis Suspected
  - If chronic pancreatitis is suspected as evidenced by recurrent characteristic pancreatic pain, symptoms of maldigestion/malabsorption that improve with digestive enzymes, and/or abnormal laboratory studies suggesting pancreatic dysfunction, then plain abdominal x-ray (KUB) and ultrasound should be performed initially.
  - If x-ray and ultrasound are nondiagnostic for changes consistent with chronic pancreatitis, then CT abdomen without and with contrast (CPT®74170) or MRCP (See AB-1 General Guidelines for coding guidelines for MRCP) can be performed if findings will affect management decisions.
    - Diagnostic findings on ultrasound include pancreatic stones as evidenced by intra-pancreatic hyperreflective echoes with acoustic shadows.
  - If CT or MRCP is nondiagnostic, then endoscopic ultrasound with biopsy should be performed.
    - Diagnostic findings on CT include pancreatic stones as evidenced by intra-pancreatic calcifications.

- Reference:
  - Gastroenterology 2001;120:682-707

- Known Chronic Pancreatitis Including Hereditary Pancreatitis:
  - There is no evidence-based data supporting screening for pancreatic cancer in patients with a history of chronic pancreatitis, including those with hereditary pancreatitis.*
    - *Screening for pancreatic cancer, U.S. Preventive Services Task Force, Screening for Pancreatic Cancer, Updated February 2004

SPLEEN

AB-40~SPLEEN

- Splenomegaly is usually the result of systemic disease, and diagnostic studies are directed toward identifying the causative disease.
  - Complete blood count with differential, LFT’s, and peripheral blood smear examination should be performed prior to considering advanced imaging.
  - Suspected splenomegaly should be evaluated by ultrasound initially.*
    - *ACR Practice Guidelines for the performance of an ultrasound examination of the abdomen or retroperitoneum, revised 2007
If ultrasound is indeterminate or shows an abnormality, CT abdomen without and with contrast (CPT®74170) can be performed.*

- If ultrasound is indeterminate, MRI can be used in pregnant women for further evaluation.
- If CT is indeterminate or contraindicated, MRI abdomen without and with contrast (CPT®74183) can be performed.

Incidental Finding of Splenic Lesion(s):
- If an incidental splenic lesion is seen on a non-abdominal imaging study (e.g. chest CT, thoracic MRI, etc.), abdominal ultrasound should be performed if the lesion has cystic qualities.
- CT abdomen (either with contrast [CPT®74160] or without and with contrast [CPT®74170]) can be performed if ultrasound is nondiagnostic or the lesion does not have cystic qualities.
- If CT is indeterminate or contraindicated, MRI abdomen without and with contrast (CPT®74183) can be performed.
- There is no evidence-based data to support performing serial CT or MRI scans to follow patients with incidental splenic lesions.

Trauma:
- CT scans of the abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) are indicated in patients with blunt abdominal trauma with suspected splenic rupture or in patients with penetrating trauma to the left upper quadrant.

RENAL (ACUTE FLANK PAIN, RULE OUT RENAL STONE- SEE AB-5)

<table>
<thead>
<tr>
<th>AB-41~INDETERMINATE RENAL LESION</th>
</tr>
</thead>
</table>

- Newly discovered renal mass > 1cm (indeterminate by the initial test):
  - Ultrasound should be performed initially.
    - If the lesion is consistent with a simple cyst on ultrasound (spherical or ovoid shape, absence of internal echoes, presence of a thin smooth wall, enhancement of the posterior wall) no further imaging is indicated.*
      *Am Fam Physician 2001;63:288-294 and 299
  - Lesions > 1cm that are not characterized as a simple cyst by ultrasound can be evaluated by CT of the abdomen without and with contrast (CPT®74170).
    - If the patient cannot tolerate IV contrast, then MRI of the abdomen without and with contrast (CPT®74183) is appropriate.
  - If CT or MRI characterizes the lesion as benign, no further imaging is necessary
  - If the initial follow-up CT or MRI is still indeterminate, follow-up imaging should be performed in 3 to 6 months, then annually for 5 years in older patients. In younger patients, longer annual follow-up is needed.*
      *Radiographics 2004;24:5101-5115
If a lesion has been characterized as a hyperdense renal cyst, follow-up CT scan should be performed in 3 to 6 months.

- Newly discovered renal mass < 1 cm
  - CT abdomen without and with contrast (CPT®74170) with ultra-thin cuts should be performed
    - If CT demonstrates a simple cyst or other benign lesion, no further imaging is necessary
  - If CT is indeterminate, MRI abdomen without and with contrast (CPT®74183) can be performed.
    - If MRI demonstrates a benign lesion, no further imaging is necessary

- If the initial follow-up CT or MRI is still indeterminate, follow-up imaging should be performed in 3 to 6 months, then annually for 5 years in older patients. In younger patients, longer annual follow-up is needed.*
  *Radiographics 2004; 24:5101-5115

- If a lesion has been characterized as a hyperdense renal cyst, follow-up CT scan should be performed in 3 to 6 months.

**AB-42~RENAL FAILURE**

- Ultrasound is the preferred initial imaging study for patients with acute or chronic renal failure.
- Nephrology or Urology evaluation is helpful in evaluating patients with GFR <30 ml/min/1.73m² to determine the need for advanced imaging.*
  *ACR Appropriateness Criteria, Renal failure, 2008

**AB-43~RENOVASCULAR HYPERTENSION**

- The clinical information provided should include a list of the current blood pressure medications and at least two or three serial blood pressure measurements. It is suggested that home blood pressure should be considered to rule out “white coat syndrome” and other secondary causes of resistant hypertension.*

- No imaging is required for patients with hypertension that is easily controlled with one or two blood pressure medications with the exceptions listed in “Other considerations for imaging evaluation”-see below in this section.

- In patients with uncontrolled or resistant hypertension (>140/90 without history of diabetes or renal disease or >130/80 with diabetes or renal disease on three or more blood pressure medications-including diuretics), MRA (CPT®74185) or CTA (CPT®74175) of the abdomen is indicated. It is suggested that home blood pressure should be considered to rule out “white coat syndrome” and other secondary causes of resistant hypertension.*

- Doppler ultrasound is the most cost-effective exam for screening renovascular hypertension and can be used as the initial screening tool for medically controlled
patients with clinical suspicion of renovascular disease. However, ultrasound results are highly dependant on the expertise of the local facility/radiologist.*

*AJR 2005;184:931-937

- **Other considerations for imaging evaluation:**

  Abdominal MRA (CPT®74185) or CTA (CPT®74175) may be indicated for the following:
  
  o Patients under 40 years old with hypertension, controlled or uncontrolled, to exclude fibromuscular dysplasia of the renal arteries.
  
  o Patients > age 55 with sudden onset of significant hypertension (not specifically defined but >160/100 is considered severe).
  
  o Patients with previously stable hypertension who experience progressively worsening hypertension, increase in creatinine, or worsening renal function (especially after the administration of an ACE inhibitor or with angiotensin receptor blocking agent). These are the patients that benefit most from renal artery stenting, since renal parenchyma is preserved and eventual kidney dialysis can hopefully be avoided.
  
  o Unexplained atrophic kidney or discrepancy in size between kidneys of greater than 1.5 cm.
  
  o Recurrent (flash) pulmonary edema.
  
  o Co-existing diffuse atherosclerotic vascular disease, especially in heavy smokers.
  
  o Women who develop hypertension (≥140/90) within the first 20 weeks of pregnancy should have renal artery imaging following delivery, if the hypertension persists >12 weeks post partum.

  *Current Cardiology Reports 2005;7:405-411

  *Gibson P. Hypertension and Pregnancy. Updated June 8, 2006

**URINARY TRACT**

**AB-44~HEMATURIA**

- The distinction between microhematuria and gross hematuria is no longer used as a criterion for guidelines to determine which patients need imaging evaluation.

- If a dipstick test is positive for blood, a blood creatinine level and complete urinalysis with microscopic exam should be performed prior to imaging studies.

  o The American Urological Association defines microscopic hematuria as 3 or more RBC’s per high power field from 2 of 3 urinalysis specimens.

- Women <40 years of age with evidence of urinary tract infection (urinary frequency, burning on urination, fever, elevated WBC >10,000) should receive at least a 3 day regimen of antibiotics followed by repeat complete urinalysis with microscopic exam. If the hematuria resolves, advanced imaging is not indicated.
• Patients with evidence of primary generalized renal disease (elevated creatinine or urinalysis showing red cell casts, greater than 2+ protein on dipstick, dysmorphic red blood cells, or 24 hour urine protein >500 mg per 24 hrs) should have renal ultrasound in order to determine renal volume and morphology prior to considering advanced imaging.
  o Nephrology or Urology evaluation can be helpful in determining the need for advanced imaging.
• In all remaining patients with hematuria verified by complete urinalysis with microscopic exam, and absence of acute flank pain, CT urogram (CPT® 74170 and CPT® 72194) is indicated.
• The American Urological Association recommends imaging of the upper urinary tract (CT urogram [CPT® 74170 and CPT® 72194]), urine cytology, and cystoscopy for patients over 40 years old with documented hematuria on 2 of 3 urinalysis specimens.
  o This applies to all patients over 40 years old whether there is painless hematuria or flank pain with hematuria.
  o CT studies ordered by Urology should be contrast as requested.
• Patients who have had a thorough work up for hematuria with no etiology found should have repeat urinalysis, urine cytology, and blood pressure measurements at 6, 12, 24 and 36 months. Repeat imaging is not necessary, as studies have found no cancer on repeat imaging.*

*ACR Appropriateness Criteria, Hematuria, 2008
*Am Fam Physician 2006;73:1748-1754 and 1759
Urology evaluation can be helpful in determining the need for advanced imaging in patients with recurrent urinary tract infections. Thorough diagnostic work up includes CT urogram (CPT®74170 and CPT®72194), cystoscopy, and voiding cytourethrogram. Males with first time urinary tract infection may benefit from Urology evaluation and CT urogram. Pregnant women should be evaluated initially by ultrasound and if further imaging is necessary, MRI abdomen and pelvis (contrast as requested).

**Upper Urinary Tract**

- Uncomplicated acute pyelonephritis does not require imaging prior to antibiotic treatment unless the patient has a history of kidney stones, prior renal surgery, or repeated pyelonephritis.
- No advanced imaging is indicated in patients with uncomplicated pyelonephritis.
- If there is no response to medication after 72 hours, ultrasound should be performed initially. CT without and with contrast (CPT®74170 and CPT®72194) may be indicated.
- Diabetics and immunocompromised patients should be evaluated with CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194) within 24 hours of initiating antibiotics if there is no clinical improvement.*

*ACR Appropriateness Criteria, Acute Pyelonephritis, 2008

**Lower Urinary Tract**

- Urology evaluation is helpful in women with recurrent lower urinary tract infections (2 or more infections occurring in the preceding 12 months and confirmed by cultures).
- Plain x-rays can detect bladder calculi, which can be a cause of recurrent lower tract infection, and should be the initial study.
- Complicated recurrent UTI can be evaluated with CT abdomen and pelvis without and with contrast (CPT®74170 and CPT®72194). The combination of ultrasound and plain x-rays can be as accurate as CT, but ultrasound quality is not as consistent and is operator dependent.
- Unexplained dysuria (failure of conservative treatment and/or presence of normal urinalysis) and/or increased urinary frequency may benefit from Urology evaluation and cystoscopy prior to considering advanced imaging.
- Suspected urethral diverticulum should be evaluated by voiding cystourethrogramy, retrograde urethrogram, or ultrasound.
  - Pelvic MRI without and with contrast (CPT®72197) can be performed in equivocal cases.

*ACR Appropriateness Criteria, Recurrent lower urinary tract infection in women, 2008

- Also see PV-12~Periurethral Cysts and Urethral Diverticula in the Pelvis Imaging Guidelines.
**AB-46~PATENT URACHUS**

- **Patent urachus** which is suspected due to umbilical discharge should initially be evaluated by ultrasound.
  - The urachus is a “tube” connecting the fetal bladder to the umbilical cord. It is usually obliterated during fetal growth, but if it remains patent, there can be a connection between the bladder and the umbilicus.
- CT Pelvis with contrast (CPT®72193) can be performed if ultrasound is equivocal or if needed for surgical planning.
EVIDENCE BASED CLINICAL SUPPORT

Evidence Based Clinical Support
AB-2~ABDOMINAL PAIN

- After low back, headache, and musculoskeletal pain, abdominal pain is the fourth most frequent chronic pain syndrome. In many patients, even an extensive work up does not reveal the cause of pain.
- A review of over 10,000 patients with acute abdominal pain found that 28% had appendicitis, 9.7% had cholecystitis, 4.1% had small bowel obstruction, 4% had a gynecological disorder, 2.9% had pancreatitis, 2.9% had renal colic, 2.5% had peptic ulcer disease, 1.5% had cancer, 1.5% had diverticular disease, and 9% had other conditions. A specific diagnosis was not established in 34% of cases.*
- A review of 70 patients with chronic abdominal pain for greater than 12 weeks who underwent laparoscopy showed adhesions in 39 patients, hernia in 13, adhesions from adjacent structures in 6, appendix pathology in 5, endometriosis in 3, gallbladder pathology in 2, and 10 patients with no obvious pathology.
- After 12 weeks postoperatively, 71% of patients had long term relief of pain.*
  *Surgery* 2003 Oct;134(4):549-554
- Questions such as “Does taking a deep breath aggravate your symptoms?” and “Does twisting your back aggravate your symptoms?” are a positive indication of abdominal symptoms of musculoskeletal origin.

Evidence Based Clinical Support
AB-5~FLANK PAIN, RULE OUT RENAL STONE

- The classic presentation of renal stone disease involves acute onset of flank pain sometimes with radiation to the groin, hematuria, and possible nausea/vomiting.
- Calcium stones comprise 85% of all kidney stones and are composed of calcium oxalate and phosphate. The majority of calcium stones are radiopaque (i.e. they would show up on a plain x-ray), but not all.
- Uric acid stones and cystine stones comprise 9% of all kidney stones and are radiolucent and thus cannot be seen on plain x-ray.
- Most patients who form one calcium stone will eventually form another, with the average rate of new stone formation about one stone every 2 or 3 years. Calcium stone disease is strongly familial.
- The absence of hematuria does not rule out a kidney stone.
- Unenhanced CT has a very high, >95% sensitivity and specificity for urinary tract calculi and allows for delineation of other potential causes of the patient’s symptoms. In addition, CT scan accurately determines the presence of hydronephrosis caused by urethral obstruction due to kidney stones.
Evidence Based Clinical Support
AB-11~RIGHT LOWER QUADRANT PAIN, RULE OUT APPENDICITIS

- The differential diagnosis of acute right lower quadrant pain includes appendicitis, Crohn’s disease, epiploic appendagitis, infectious ileitis, mesenteric adenitis, omental infarction, right-sided diverticulitis, Meckel’s diverticulitis, and intestinal ischemia.
- The diagnosis of appendicitis is generally made by patient history, physical exam findings, and lab results (including urinalysis in all patients and pregnancy test for women of childbearing age).
- The classic presentation of appendicitis includes sudden onset of epigastric/periumbilical pain which then moves to the right lower quadrant, possible nausea/vomiting, low grade fever (100-101 degrees), leukocytosis (11,000-15,000), and localized tenderness/guarding/rebound in the right lower quadrant at McBurney’s point. However, low grade fever is present in only 67%-69% of patients.
- Patients with atypical clinical findings or an unclear diagnosis may require imaging with CT or ultrasound.
- CT can decrease the false-negative rate for appendectomy. In a study of 146 patients with clinically suspected appendicitis who also underwent CT scanning, the false-negative appendectomy rate was only 4%* compared to the historical false negative rate of 20% in patients taken to surgery on clinical suspicion alone. *Am J Gastroenterol 1998;93:768-771
- The highest clinical misdiagnosis of appendicitis occurs in young women in whom acute gynecologic conditions are common and may mimic appendicitis.
- The sensitivity of CT and US for diagnosing acute appendicitis is 93% and 77%, respectively.*
  *Radiology 2002;225:131-136
- CT scan without contrast has a sensitivity of 86%, specificity of 98%, positive predictive value of 97%, and negative predictive value of 98% in diagnosing appendicitis.*
  *Br J Radiol 2002;75:721-725

Evidence Based Clinical Support
AB-14~BARIATRIC SURGERY

- There are a variety of methods used in bariatric, or obesity, surgery. Restrictive surgery includes vertical banded gastroplasty (using bands and staples to create a small stomach pouch), gastric banding, and laparoscopic gastric banding. Combined restrictive and malabsopitive surgery includes Roux-en-Y bypass (the jejunum or ileum is directly connected to the small stomach pouch thereby bypassing a portion of the small intestine) or biliopancreatic diversion.
- There is a relatively high (>10%) complication rate for obesity surgery.
• Complications include pulmonary embolus, infection, and leakage from the GI tract, bleeding, bowel obstruction, incisional hernias and gallstones.

Evidence Based Clinical Support
AB-19~LOWER EXTREMITY EDEMA

• Lower extremity edema is caused by venous or lymphatic obstruction.
• Unilateral lower leg swelling can be caused by deep venous thrombosis (DVT), thrombophlebitis, or even a popliteal cyst.
• Bilateral lower extremity edema can be caused by deep venous thrombosis (DVT), thrombophlebitis, chronic lymphangitis, and external compression of the iliac veins from a mass or even from a large bladder caused by prostate hypertrophy. Abdominal lesions such as a large pancreatic pseudocyst compressing the inferior vena cava can also cause lower extremity edema.
• Systemic medical conditions such as congestive heart failure, nephrotic syndrome (marked proteinuria >3.5 g/Day and severe hypoalbuminemia <2g/dL), hypothyroidism (myxedema usually manifested by pretibial edema), and even lesions in the CNS affecting the vasomotor fibers on one side of the body can cause lower extremity edema.
• There is an association between bilateral leg edema in obese primary care patients and obstructive sleep apnea and modest pulmonary hypertension.* The etiology of the leg edema is largely unknown.

Evidence Based Clinical Support
AB-21~ADRENAL CORTICAL LESIONS

• Most incidentally discovered adrenal nodules (incidentalomas) are benign if there is no underlying malignancy, the lesion is less than 3 cm in diameter, and there are no symptoms.
• The incidence of these lesions in the general population is 2%.
• One in 4000 adrenal masses is malignant. Masses <3cm are rarely functional tumors. 25% of adrenal masses >6cm are adrenal cortical cancer.
• The mean attenuation value of adrenal adenomas is 8 HU ± 18. 29% of adenomas have attenuation values higher than10 HU.
• Tumors found incidentally in the adrenal glands on CT are likely to represent adenomas or hyperplasia if they are <4 cm in diameter and have HU values <20.*

*J Clin Endocrinol Metab 2005;90:871-877
• Mean attenuation value of metastases to the adrenal gland is 34 HU ± 11.*

• Plasma free metanephrines are the most sensitive biochemical test for pheochromocytoma.
• Over 50% washout of contrast material on a 10-minute delayed CT scan is diagnostic of an adenoma. This is the most sensitive and specific study because
it can detect both lipid rich (70% of adenomas) and lipid poor (30% of adenomas) adenomas.

- Two large retrospective studies of adrenal masses, found incidentally on other imaging, reported no cancers in a 24 month period of time following the original discovery of the mass in patients with no personal history of cancer and no evidence of a hormone secreting adrenal tumor.

---

### Evidence Based Clinical Support

**AB-23~ABDOMINAL AORTIC ANEURYSM (AAA) and ILIAC ARTERY ANEURYSM (IAA) POST ENDOVASCULAR or OPEN AORTIC REPAIR**

- Patient selection for endovascular AAA repair is based on the anatomy of the aneurysm. Precise measurements of the aorta and iliac arteries must be obtained.
- Women with smaller diameter AAA tend to rupture earlier.
- A commonly used preoperative protocol involves CT scan of the abdomen and pelvis or CTA, followed by aortography.
- Another protocol uses ultrasound and MRA of the abdomen and pelvis with contrast.
- Endoleak, in which there is persistent bleeding into the original aneurysm sac, is the most common complication of endovascular AAA repair and occurs in 2.4%-45% of patients. The presence of an endoleak can cause progressive enlargement of the AAA and eventual rupture. Therefore, early detection and monitoring of endoleaks is important.
- Postoperative imaging protocols generally involve CT scan of the abdomen and pelvis within the first 30 days postoperatively, at 6 months, 12 months, and every year thereafter.
- Since the durability of endovascular grafts is not yet known, surveillance CT scans should continue every year indefinitely, since some grafts have developed fractures, suture disruption, and wear holes over time.
- Several studies comparing duplex ultrasound to CT scan in the surveillance of endovascular aneurysm repair have shown poor sensitivity of ultrasound (42.9%) compared with CT scan in detecting endoleaks.

### Evidence Based Clinical Support

**AB-28~INFLAMMATORY BOWEL DISEASE RULE OUT CROHN’S DISEASE or ULCERATIVE COLITIS**

- MRI is preferable in patients expected to need repeated follow-up exams.
- Small bowel Crohn’s disease may benefit from capsule endoscopy and/or CT enterography. Capsule endoscopy should be avoided in known or suspected obstructive disease. With either test barium study and ileoscopy should precede their use.
Evidence Based Clinical Support

AB-30~CT COLONOGRAPHY (CTC)

- Out of the 3120 patients who underwent primary VC screening, 87% of the results were negative, 13% were positive, and 8% of patients underwent therapeutic conventional colonoscopy. Patients were referred for polypectomy if VC showed a polyp at least 6mm in size. Patients with smaller polyps (6-9mm) were offered the option of continued surveillance with VC or polypectomy.*
  

- A large comparative study has shown that CT colonography produced similar rates of detection for advanced neoplasia as conventional colonoscopy and is an effective method for colorectal screening.
  - Although these results support the efficacy and safety of CTC for colorectal cancer screening, there are only limited follow-up data available so far for patients who underwent CTC and opted to have follow-up surveillance screening for polyps 6 to 9 mm in size.
  - In addition, specific criteria need to be developed to ensure that physicians are adequately trained and quality metrics for programs are in place.
  - Reference:
    

Evidence Based Clinical Support

AB-31~CIRRHOSIS AND LIVER SCREENING FOR HEPATOCELLULAR CARCINOMA (HCC); LIVER TRANSPLANT

- Worldwide, 90% of cases of hepatocellular carcinoma (HCC) occur in patients with cirrhosis, with an annual incidence in cirrhotics of 2%-6%. In the U.S., 56% of cases of hepatocellular carcinoma occur in patients with cirrhosis.
- Risk factors for HCC in cirrhotics are male gender, age >50, macronodular cirrhosis, and large cell dysplasia.
- Hemochromatosis is associated with a substantial risk of hepatocellular carcinoma once cirrhosis has developed. Patients with alcoholic cirrhosis, alpha antitrypsin deficiency, or tyrosinemia are also at increased risk of hepatocellular carcinoma.
- HCC is most prevalent in patients with cirrhosis due to hepatitis B and especially hepatitis C. (Hepatitis C was the etiology of cirrhosis in 63% of patients with HCC in one study).
- A study comparing screening alpha-fetoprotein (AFP), ultrasound, and CT scan in patients with established cirrhosis found that the sensitivity of CT scan (88%) was significantly higher than AFP >20 ng/ml (62%) and ultrasound (59%) for detecting HCC.*
  
  *Am J Gastroenterol 1999 Oct;94(10):2988-2993

- HCC is best detected by triple phase CT scanning.
Clinically unsuspected HCC was found in 14% of 430 patients with cirrhosis referred for liver transplantation.* In this study, the sensitivity of triphasic CT was only 59%.

*Radiology 2000 Dec;217(3):743-749

Serum AFP levels higher than 300-500 micrograms/L are very specific for HCC, but serum AFP values are not sensitive for detection of most small tumors. In one study, 55% of patients with cirrhosis and HCC had normal serum AFP levels.

Liver lesions can be categorized as cystic or solid. Cystic lesions are usually benign. The most common benign lesions are hemangioma, focal nodular hyperplasia, and hepatic adenoma.

Malignant lesions can be primary hepatocellular carcinoma or metastases from other primary tumors.

Hemangiomas are congenital vascular malformations and are the most common solid benign hepatic tumors.

The finding of an incidental pancreatic cyst is common. A retrospective study of incidental cysts, defined as mucinous cystic neoplasm or branched intraductal papillary mucinous neoplasm, found no change in lesions less than 3 cm over 2 years of follow up and recommended that asymptomatic individuals without evidence of main pancreatic duct dilation or without intracystic or mural nodules could be followed at 2 year intervals from the date the initial cyst was diagnosed. Any growth, symptoms or initial evidence suspicious for malignancy should undergo EUS or have surgical excision.

*Am J Gastroenterol 2008 July;103(7):1657-1662

The most common tumors to metastasize to the pancreas are renal cell carcinoma and lung carcinoma. Melanoma, breast, ovarian, colon, and thyroid carcinoma can also metastasize to the pancreas.

Pseudocysts are collections of tissue, fluid, debris, pancreatic enzymes, and blood which develop one to four weeks after the onset of acute pancreatitis. They form in approximately 15% of patients with acute pancreatitis. Pseudocysts are preceded by pancreatitis in 90% of cases and by trauma in 10%. Pseudocysts resolve spontaneously in 40%-50% of patients. Therefore, up to 50% of pseudocysts can be managed nonoperatively.

Pancreatic pseudocysts larger than 5 cm or present for longer than six weeks should be considered for drainage.
Evidence Based Clinical Support
AB-41~INDETERMINATE RENAL LESION

- A retrospective study of 102 sonographically indeterminate renal masses which were then evaluated by CT scan showed that 13% were malignant, 85% were benign, and 2% remained indeterminate.*
- CT remains the major method of imaging and characterizing cystic renal lesions. A change of <10 HU from pre to post contrast images is usually considered typical of a benign cyst.*
  *Radiographics 2004;24:5101-5115

Evidence Based Clinical Support
AB-43~RENOVASCULAR HYPERTENSION

- In the general hypertensive population, the prevalence of renovascular disease varies between 1% and 5%. However, the prevalence of renal artery stenosis (RAS) increases to 20%-40% with specific clinical characteristics.
- Patients with the following clinical features associated with renal artery stenosis (RAS) are often considered for further evaluation:*
  - Abrupt onset of hypertension before age 40 (suggestive of fibromuscular dysplasia).
  - Abrupt onset of hypertension or progressive worsening of hypertension at or after age 50 (suggestive of atherosclerotic RAS).
  - Accelerated or malignant hypertension (defined as very high blood pressure with end organ damage such as papilledema, retinal hemorrhage, heart failure, renal failure, or hypertensive encephalopathy).
  - Refractory hypertension (diastolic blood pressure consistently >100 but the JNC-7* has defined refractory as BP >140/90 for patients without diabetes or renal disease and >130/80 for patients with diabetes or renal disease on three or more blood pressure medications).
  - Unexplained azotemia (abnormally high BUN), or azotemia induced by treatment with ACE inhibitors is suggestive of atherosclerotic RAS.
  - Unilateral small kidney.
  - Abdominal bruit, flank bruit, or both.
  - Carotid, coronary, or peripheral vascular disease.
  - Unexplained congestive heart failure with normal left ventricular function, or acute pulmonary edema.
- Atherosclerotic renal artery disease is present in 7% of the general population over age 65, and in 20%-45% of patients with coronary artery disease or aortoiliac disease.
- JNC-7* has defined severe hypertension to include the importance of systolic blood pressure (BP). Based on their recommendations, the definition of
uncontrolled BP has been redefined as >140/90 for patients without diabetes or renal disease, and >130/80 for patients with diabetes or renal disease. Systolic hypertension is associated with the prediction of hypertension complications.

- Medication-resistant hypertension in one study is defined as no decrease in blood pressure after institution of two-drug therapy, and uncontrolled hypertension is defined as diastolic blood pressure>110. The prevalence of renal artery stenosis in the medication-resistant hypertension population is 20%.*
  *AJR 2003 Dec;181:1653-1661*
- The clinical success rate of renal angioplasty of atherosclerotic stenosis is 40%-70%.
- The positive predictive value of MRA for predicting clinical success after angioplasty is very low. The advantage of MRA is the high negative predictive value (i.e. absence of false-negative exams).*
  *AJR 2005;184:931-937*
- Captopril renography has 92% sensitivity in detecting renal artery stenosis, but has decreased accuracy in patients with bilateral disease or renal impairment. In addition, interference from concurrent antihypertensive medication, especially ACE inhibitors, and the lack of facilities equipped to perform this study, have limited the availability of this imaging study.*
- Ultrasound has a sensitivity of 56%-95% in detecting renal artery stenosis, but is highly operator dependent.
- There is no statistically significant difference between MR angiogram and multidetector row CT angiogram in the detection of hemodynamically significant RAS. (MRA sensitivity 98%, specificity 94%; CTA sensitivity 96%, specificity 96%).*
  *Radiology 2003 March;226(3):798-811*
- Patients with significant renal artery stenosis on MRA or CTA still need to have conventional arteriography performed if stents are placed.

**Evidence Based Clinical Support**

**AB-44—HEMATURIA**

- Urologic cancers (mainly of bladder and prostate) account for approximately 5% of cases of microscopic hematuria.
- In a referral-based study of 100 men less than 40 years old with microscopic hematuria, no bladder cancers were identified by cystoscopy.*
  *N Engl J Med 2003;348:2330-2338*
